APPENDIX F - EnergyPro Results / Energy Cost Budget

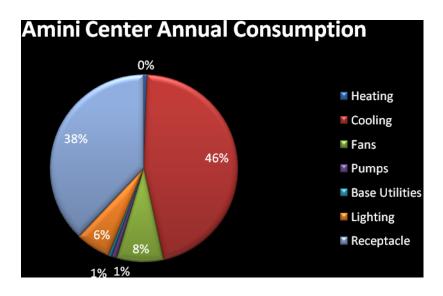

Executive Summary

Many factors and assumptions are taken into account when trying to determine the cooling load needed for a room or building. Some factors include climate data, envelope loads, internal loads, and ventilation air loads. To accurately estimate the loads of an entire building would take an engineer hours to calculate by hand. Due to advancements in technology, computer programs exist to help an engineer calculate cooling capacities much quicker. One particular program, TraneTrace 700, was used for the first part of this report to simulate the load needed to cool the Amini Medical Center.

After inputting the building envelope, people, lighting, plug load, and climate data for the Amini Center, based on the construction documents, the program then calculated the cooling capacities I would expect to see for this building. This particular simulation involved only 35,000 ft² of the center due to empty shell plans for the entire third floor. The simulation looked at two units serving lab areas on the first floor and another unit serving administrative and office areas on the remaining first floor and second floor. Overall for the space, the cooling capacity for the lab areas ranged from 115 - 190 ft²/ton, while the office area unit saw about 471 ft²/ton. This difference in capacity makes sense in this building because the lab spaces see a much higher internal load due to the many pieces of equipment contained in them.

The second part of this report investigates the energy consumption and cost associated with running the Amini Medical Center for one calendar year. To aid in estimating the consumption and cost to run this facility, the TraneTrace 700 program required more input.

To try and accurately model the space, schedules were created to simulate occupancy, lighting, equipment, ventilation, utility rate schedules, and other factors that have an effect on energy consumption and cost. After plants were created and all schedules were assigned, the program simulated the equipment consumption and produced the dollar figure it would cost to run this facility based on the inputs. For my simulation the energy consumption broke down as follows:

Total cost to run this facility was calculated to be \$113,208 per year which ends up being \$3.26/ft².

For the overall experience of using Energy Models, I believe they can be very beneficial tools to help produce information in a short amount of time. Due to the amount of input needed to

generate results, errors seem easy to come by. I don't believe they are good tools for estimating a building's electric bill due to the many assumptions that have to be made. Because this was a fast paced model simulation, I don't believe I spent enough time to develop a truly accurate figures. The values generated, however, do provide much insight into the building and how it will function.

Load Estimation

To aid in determining the cooling loads required for the Amini Medical Center, the TraneTrace 700 program was utilized. Due to the third floor remaining vacant on the construction documents received, this area was not included in the following analysis. This estimate will only include the cooling loads required for three air-handling units (AHUs) serving the first and second floors, along with fan coil units (FCUs) serving special need areas of the building. For a schematic of theses units and the areas they serve, please refer to Appendix A.

To determine the loads required for each HVAC unit, building envelope load, occupancy load, lighting load, plug load, ventilation air load, and climatic data were input into the program using the construction documents as a reference.

<u>Inputs</u>

Building Envelope:

The Amini Center building envelope consisted of three typical wall types and one specific glazing type. The u-values entered into the program for these wall types and glazing values can be viewed below. Refer to Appendix B for a more detailed breakdown of these entered values.

Construction	U-Value Btu/h*ft2*F	SC
Stone Wall	0.043	-
Fire/Stucco Wall	0.039	-
Spandrel Glass Wall	0.045	-
Glazing	0.26	0.43

Occupancy:

For this estimation, occupancy for each room was taken from the Architectural drawings. Maximum load was assumed to be the maximum number of chairs or seating locations in each room. Each person was assumed to giver off 250 Btu's sensible heat and 200 Btu's latent heat.

Lighting:

Lighting for every space was assumed to 0.85 W/ft², which happens to be the designed lighting density for this building, as seen in Technical Assignment 1.

Plug Load:

Plug load, or room equipment heat load, for this building was estimated on a room by room basis. Due to the assortment of equipment in lab areas and IT rooms, a general W/ft² load would produce inaccurate results. For these lab areas, I referred to a LEED energy model created by the design team and inserted the loads the design team used.

For general office areas, I estimated the equipment heat loads for computers, printers, copiers, etc. Refer to the Table below for some general equipment loads that were assumed in the office spaces.

Equipment	Heat Load Watts	Equipment	Heat Load Watts
Computer	155	Refrigerator	300
Desktop Printer	100	Microwave	300
Copier	400	Toaster	100
Fax Machines	100	Coffee Maker	200

Ventilation Air:

Supply air for each room was input based on the construction documents. In doing so, each AHU and FCU ventilation percentage was also input based on the minimum outdoor air (OA) quantity listed on the drawing schedules.

Climate Data:

The Amini Medical is being constructed in Duarte, California, a suburb of Los Angeles. For this estimation the Trace program is equipped with regional weather data from around the world. The weather data selected for this project was Pasadena, Ca, 10 miles away from this building site. Design conditions for this region are as follows:

Inc	door Co	onditions		Outdoor Conditions							
Sun	nmer	Winter	Sun	nmer	Winter	Clearn	ess	Grou Reflecta	-	CO2 Level	
DB	RH	DB	DB WB		DB	Summer	Winter	Summer	Winter	PPM	
72	50	72	95 68		29	1.05	0.95	0.2	0.2	400	

Output Results

The following table summarizes the results of my cooling load estimation and compares them to the capacities scheduled on the design documents. For a more detailed breakdown of the Trace load capacities, refer to Appendix C.

	Trace	e Program	Design	Documents		Trace	e Program	Design Documents		
Unit	Total	Sensible	Total Sensible		Unit	Total	Sensible	Total	Sensible	
	MBH	MBH	MBH MBH			MBH	MBH	MBH	MBH	
AHU-1	259.0	145.5	277.6	264.0	AHU-2	392.5	319.9	453.8	440.1	
AHU-3	608.3	525.0	751.0	680.6	FCU-1-1	5.0	4.9	10.8	6.2	
FCU-1-2	15.1	15.1	47.3	38.3	FCU-1-3	45.2	45.2	100.4	55.2	
FCU-1-4	7.6	7.5	17.4	10.4	FCU-1-5	132.1	97.5	91.1	82.9	
FCU-2-1	49.4	49.4	72.4	58.6	FCU-2-2	17.3	17.3	3.5	2.8	
FCU-2-3	9.3	9.3	3.5	2.8	FCU-2-4	10.4	10.4	8.1	6.5	

Discussion:

AHUs

In comparison to the estimated load calculations, AHU-1, 2 & 3 scheduled vary in total capacity by 6.7%, 13.5%, and 19% respectively. On a $\rm ft^2/ton$ basis the differences between estimated and calculated are as follows:

	Estimated	Design Documents
Unit	ft2/ton	ft2/ton
AHU-1	115	107
AHU-2	191	165
AHU-3	471	382

In viewing these calculations it appears that AHU-1 is pretty close to the actual scheduled unit and AHUs 2 & 3 are estimated to be a significant tonnage lower in capacity.

These capacity differences can be caused by a countless number of reasons, or a combination of reasons. Some reasons for the lower estimated values could include climate data, indoor design conditions, underestimating internal loads, and other differences, even calculation methodology.

FCUs

Because the loads in the rooms the fan coil units serve were taken from the design engineer EnergyPro simulation, the loads should match what was scheduled. Looking at the table above however shows that some FCUs are close to the scheduled capacities while others are well below or well over the design documents.

For these rooms, load calculations are hard to estimate and should be supplied to the design engineer to avoid any over or under sizing of equipment. The values estimated/taken from EnergyPro program could be old values that were initially intended for the rooms but were changed later during design.

Energy Analysis

This part of the report focuses on the energy used and the estimated cost to run the Amini Medical Center for one calendar year. The simulation program used for this analysis was the TraneTrace 700 program. The model described in the load estimation above is the exact model being run for the energy study.

Inputs

Systems & Plants:

For this simulation all air handling units were modeled as VAV Reheat systems, 30% minimum flow. Specific areas containing constant volume units had the default 30% minimum flow reset for 100% minimum flow. All supply air and outdoor air quantities for these units were input and locked to match the design documents. Fan coil units were modeled as such with the supply air set by the construction documents air flows.

Because this building is served by a central campus heating and cooling plant, the energy simulation was modeled as a purchased chilled water system and a purchased steam system. The energy analysis also includes the chilled water pumps and heating water pumps that run water throughout the building.

All fans including supply, return, exhaust, toilet exhaust and lab exhaust fans were modeled and input based on the BHP and air quantity. All fan energies were input as KW/cfm.

Exterior lighting was accounted for as a base utility, setting total KW for the lights on a schedule.

Operation Schedules:

Because buildings are not occupied 24/7 and all equipment and lighting is not in operation 24/7, schedules need to be made to try and simulate the actual building operation. For the Amini Medical Center, the design engineer created a model in EnergyPro to simulate the buildings operation. For this report, I looked over the schedules the engineer made and created the same schedules in this program. Please refer to Appendix D for all the schedules that were created.

Fuel Costs:

To estimate the actual cost that the building owner might see, energy rates need to be defined setting the cost per energy rate. For this building in Duarte California, the rate structure for SCE was used. Refer to the end of Appendix D for this rate schedule.

<u>Outputs</u>

Energy Consumption:

The energy consumption shown in the table below gives the break down for the Amini Medical Center.

	Elec Consumption (kwh)	Purchased Chilled Water (kBtu)	Purchased Steam (kBtu)	% Total Energy	Total Building Energy (kBtu/yr)	Total Source Energy (kBtu/yr)
Primary Htg			26,204	0.54	26,204	34,939
Other Htg Accessories	249			0.02	849	2,548
Primary Cooling		2,233,676		46.07	2,233,676	1,718,212
Supply Fans	113,671			8.00	387,959	1,163,993
Pumps	13,050			0.92	44,539	133,631
Base Utilities	8,038			0.57	27,434	82,310
Lighting	85,055			5.99	290,294	870,968
Receptacle	538,374			37.90	1,837,470	5,512,961
Totals	758,437	2,233,676	26,204	100	4,848,425	9,519,562

From this table it is easy to conclude to conclude that this is a cooling dominated building. From the weather conditions, internal loads, and envelope load; it does make sense that the building will be in cooling mode most of the time.

Annual Operation Cost:

According to the model simulation, it will cost the Amini Medical Center \$113,208 per year to operate under the design conditions above assuming no change to energy prices throughout the year. The annual breakdown per square foot ends up being 3.26\$/ft². Considering only the first two floors of this building were modeled, and the occupancy of these floors, I feel the operation cost does give a relatively accurate estimate for the building type. For the Trace Monthly Utility Costs, refer to Appendix E.

Design Engineer Energy Simulation:

Because this project is going for a LEED Gold rating, the design engineer produced an energy model comparison showing the saving of the Amini Medical Center design compared to a baseline building specified by LEED. The design engineer's energy model for the Amini Center resulted in a similar breakdown of energy use as shown in this report. The report indicates the building is a cooling dominated building. The cost indicated by the engineer's report indicates an annual energy cost of \$3.84/ft² which is relatively close to the annual energy cost I had simulated. Please Refer to Appendix F for the EnergyPro reports and my simulated Energy/Cost budget.

Discussion:

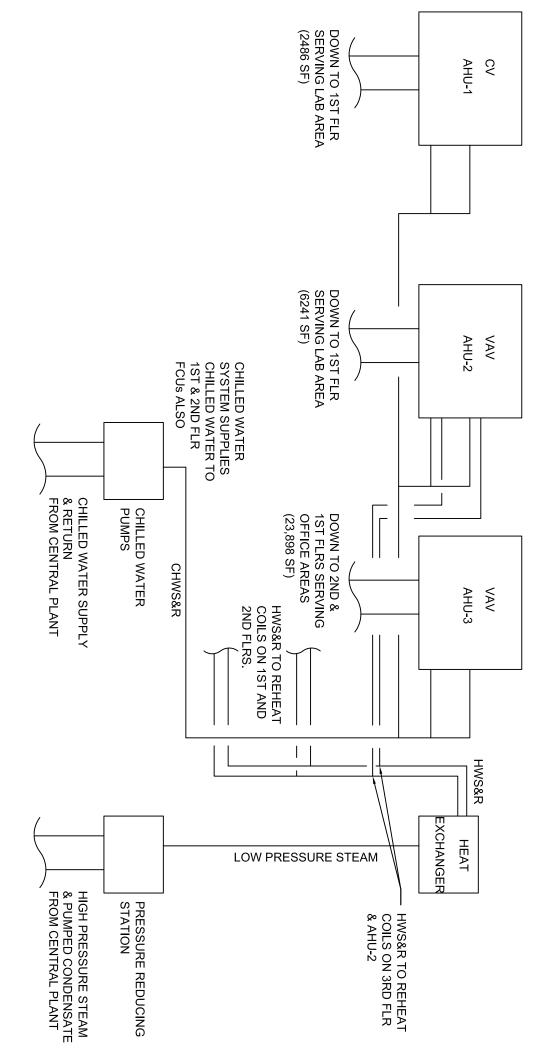

For the overall experience of using Energy Models, I believe they can be very beneficial tools to help produce information in a short amount of time. Due to the amount of input needed to generate results, errors seem easy to come by. I don't believe they are good tools for estimating a building's energy bill due to the many assumptions that have to be made. Because this was a fast paced model simulation, I don't believe I spent enough time to develop a truly accurate figures. The values generated, however, do provide much insight into the building and how it will function.
