## **Executive Summary**

The focus of this report is to provide an in depth look at the mechanical systems for the Amini Medical center and provide a personal critique.

This evaluation will provide a brief overview of the project then discuss aspects that influenced the current design. The current system will then be described in detail with references to maps and diagrams that will act as visual aides. After the Amini Center system has been described, the size, load, and energy impact of the system will be discussed and evaluated.

To conclude the report, a critique of the system has been provided. Overall, the Amini Center's Mechanical system seems to meet all the requirements of the building. It is a versatile system which provides ample control to keep people comfortable in the zones that were created. The system also employs energy saving features to minimize its effect on the environment. Overall, I believe the Amini Center's design to be a very good one.

## Project Overview

#### **Building Overview**

The Amini Medical Center is the newest addition to the City of Hope campus community located in the Los Angeles, CA suburbs. The community's main functions include cancer research, treatment and education. The Amini facility's role as a part of this community includes blood collection, analysis, processing, transfusion, and storage.

To accommodate the building functions, the Amini Center is designed as a 3 story, 60,000 square foot complex which sits on the East side of campus. (Refer to page 1 of Appendix A for a vicinity map) The floors of the facility are broken down as follows:

Amini Center 1 <sup>st</sup> Floor Breakdown								
Room Types	Area (ft <sup>2</sup> )	Function						
Stem Cell Lab/ Support Area	2,500	Biomedical Research and testing						
Cryogen Freezer	1,700	Stem Cell / Blood storage						
Blood Processing Area/ Freezers	5,300	Blood Processing, testing, logistic work, & temp. storage						
Office Space	1,650	Administrative duties						
Break Room	320	Making food/ eating						
Mechanical/Electrical/IT	1,250	Equip Rooms/Data Centers						
Transition/Storage/Restroom	5,800	Storage and walk through areas						

Amini Center 2 <sup>nd</sup> Floor Breakdown								
Room Types	Area (ft <sup>2</sup> )	Function						
Blood Donation / Transfusion Bays	6,200	Extracting/giving blood from/to donors/patients						
Office Space	4,500	Administrative duties						
Reception Area	540	Waiting and filling out paperwork						
Conference Room	620	Meetings/Training						
Break Room	520	Making food/ eating						
Mechanical/Electrical/IT	450	Equip Rooms/Data Centers						
Transition/Storage/Restroom	5,550	Storage and walk through areas						

The third floor of the Amini complex is scheduled to become office space in the future; however, due to the strict budget constraints, the third floor fit-out was not included with this construction submission and, therefore, was not incorporated in this evaluation.

#### Mechanical Systems Overview

The cooling for this building is provided by a chilled water system while the heating loads are met by converting steam to hot water (HW) for use by HW coils in the air systems.

The bulk of the 1<sup>st</sup> and 2<sup>nd</sup> floors of the Amini Center are served by three custom, water cooled, Air Handling Units (AHUs) located on the roof. Small horizontal, water cooled, Fan Coil Units (FCUs), located in the ceiling plenums, serve the remaining areas not being served by an AHU. The areas served by the AHUs are broken down as follows: AHU-1 serves the Stem Cell Lab and support areas located on the 1<sup>st</sup> floor. AHU-2 serves the Blood Processing area and the Cryogen Freezer on the 1<sup>st</sup> floor. All remaining spaces on the 1<sup>st</sup> and 2<sup>nd</sup> floors are served by AHU-3. Refer to pages 2 and 3 of Appendix A for the outline of AHUs and FCUs service areas. A further

discussion and more extensive breakdown of the Amini Center's mechanical systems can be viewed later in this evaluation.

## Mechanical Systems Design Influences

Many factors have to be taken into account when designing the mechanical system(s) for any building. Site, utilities, size, occupancy, codes, and owner requirements are just a few factors. This section of the evaluation will examine some of the factors that influenced the mechanical systems of the Amini Center.

#### **Owner/Occupancy Requirements**

In the design phase of this project, the engineer was presented with requirements due to the sensitive nature of certain rooms. Some of the requirements that needed to be met were as follows:

- The AHUs for this project are required to have both a 15% efficient pre-filter and 95% efficient final filter.
- All AHUs shall be sized to include 15% spare capacity
- AHU-1, serving the Stem Cell Lab, shall be designed to provide 20 Air Changes per Hour (ACH) for a 10,000/100,000 clean room
- AHU-2, serving the Blood Processing Area and Cryo Freezer, will need redundancy to ensure the Cryo Freezer room does not lose any capacity.
- Chilled water system for this building shall have 100% redundancy.
- Chilled water and heating capacities/pumps shall include the capacities for the future 3<sup>rd</sup> floor units.

All the above requirements were taken from meeting minutes the design engineer had with the owner and others in regards to the HVAC design approach.

#### Site Influences

The Amini Center is the newest building on a campus community outside Los Angeles. Because of this location, one site influence the engineers need to account for is seismic vibrations. This fact will probably not have a big effect on the system chosen, but it will definitely influence the restraints and connections for securing the mechanical equipment.

Another site influence comes from being part of this already existing campus. A vicinity map of the campus can be seen on page 1 of Appendix A. For this particular campus, the existing central heating and cooling plants have been oversized to accommodate campus expansion. Because of this, the Amini Center has access to tie into an already existing chilled water loop and high pressure steam system. The site is also believed to have access to a high pressure gas line, but no equipment in the design documents require gas and a gas line cannot be located on the civil drawings.

#### Monetary Influences

As mentioned earlier in this report, monetary issues have had an effect on the design of the facility's mechanical system. Because the building owner was working with a set budget, aspects of the project had to be cut back for the initial design. These cut backs are thought to be extended to the mechanical system, however, this fact cannot be verified for this evaluation.

Two other monetary influences that had an effect on the design of the Amini Center include California's Savings by Design Program (SBD) and a LEED certification. Both of these programs/procedures offer monetary incentives for reducing the energy usage of a building; another monetary advantage for the owner. The Amini Center has applied for the SBD incentive and is also applying for a LEED-Gold Certification.

With the SBD program, the building owner will have the opportunity to receive up to \$150,000 in compensation for upgrades to the design. A LEED-Gold certification will allow the owner to apply for Federal Tax credits which could possibly save the owner millions of dollars.

#### Design Indoor/Outdoor Conditions

The indoor and outdoor conditions for the existing design were taken from the design engineer's energy model. The following table shows what the design engineer used for their load calculations in the SBD energy model. These values were used for all rooms.

	Existing Designed Conditions										
Ind	Indoor Conditions Outdoor Conditions										
Sun	nmer	Winter	Sun	nmer	Winter	er Clearness		ess Ground Reflectance		CO2 Level	
DB	RH	DB	DB	WB	DB	Summer	Winter	Summer	Winter	PPM	
72	-	72	96	-	31	31					

For the energy model simulated in Tech. Assignment 2, the following values were taken from the Trace700 weather data for Pasadena, CA. These values are as follows:

	Trace Model from Tech. Assignment 2									
Ind	Indoor Conditions Outdoor Conditions									
Sum	nmer	Winter	Sun	nmer	Winter	Clearness		ess Ground Reflectance		CO2 Level
DB	RH	DB	DB	WB	DB	Summer	Winter	Summer	Winter	PPM
72	50	72	95	68	29	1.05	0.95	0.2	0.2	400

#### Code Requirements

The existing building construction and design were dictated by the following code sources:

- 2002 County of Los Angeles Building Code
- 2005 County of Los Angeles Electrical Code
- 2002 County of Los Angeles Plumbing Code
- 2002 County of Los Angeles Mechanical Code
- 2002 County of Los Angeles Fire Code

#### Ventilation Requirements

The existing building design ventilation needs to meet the ventilation from the applicable codes above. The design engineers requirements could not obtained with the exception of the Stem Cell Lab needing 20 ACH. From the ventilation report, Tech. Assignment 1, the required outdoor air (OA) needed and provided for each RTU is as follows:

	Trace Program	Desigr	n Documents		Trace Program	Design Documents	
Unit	Input OA	Req. OA	Provided OA	Unit	Input OA	Req. OA	Provided OA
	cfm	cfm	cfm		cfm	cfm	cfm
AHU-1	4,100	1,101	4,100	AHU-2	6,200	3,025	6,200
AHU-3	6,800	4,830	6,800	FCU-1-1	0	0	0
FCU-1-2	0	30	0	FCU-1-3	0	9	0
FCU-1-4	0	0	0	FCU-1-5	1,200	14	1,200
FCU-2-1	0	15	0	FCU-2-2	0	32	0
FCU-2-3	0	18	0	FCU-2-4	0	20	0

In the table above, the required OA shown is in accordance with ASHRAE 62.1-2007, not the applicable codes the building was designed with.

#### Discussion

The many factors here are just some of the influences dug up for the Amini Medical Center project. There are many other factors that were, and could have been, taken into account in the actual design of the mechanical system. One such factor is the heat load of the many pieces of equipment located throughout this facility. Either way, the influences listed here can be viewed as the key elements in the design for the existing mechanical system.

## **Mechanical Systems Description**

A brief overview of the mechanical system was given earlier in the evaluation to describe the air systems. This section of the report will further the description by providing an in depth view of the equipment and controls from the heating & cooling plants to the air distribution systems.

#### Heating Plant & Building Heating System

#### Heating Plant

What is known about the central plant for this project is that there is high pressure steam (HPS) and steam condensate return piping (PCR) available to serve this the Amini Center. The specifics of the central plant, i.e. steam boiler capacities and types, were not attainable. Even the size of the existing steam and condensate pipes could not be obtained.

#### Building Heating System

The Amini Center converts available high pressure steam (125 psig) into hot water for the building to use. The connection points to the existing steam and condensate lines are located on the South side of the building. Because of this, a mechanical room was created on the South wall of the first floor to accommodate some of the necessary equipment and piping; this room is the location where a 4" HPS and a 2" PCR enter/leave the Amini Center.

Due to concerns for running high pressure steam throughout the building, the design engineer decided to reduce the HPS to medium pressure steam (MPS), for a domestic water heater, and low pressure steam (LPS) to run to a heat transfer package on the roof. In order to accomplish this, two pressure reducing valves (PRV) are located in the mechanical room to reduce the HPS first down to 25 psig MPS then down again to the 15 psig LPS. The MPS is taken to the Domestic water heater in the mechanical room and heats the domestic water loop from 40 degrees to 140 degrees. The LPS line is taken up to a heat transfer package (HTP) on the roof which heats the hot water loop and pumps the hot water to the air distribution systems (AHUs, and reheat coils).

Refer to page 1 of Appendix B for the Steam/Hot Water Flow Diagram. Refer to Appendix C for available schedules of the heating equipment.

#### **Cooling Plant & Building Cooling System**

#### Cooling Plant

The central cooling plant serving the Amini Center, and many other buildings, has a little more information available then the heating plan did. The central plan is composed of three centrifugal water cooled chillers and one steam absorption chiller. The schedules for these units can be viewed in Appendix C. The system is a primary/secondary system providing chilled water for a good portion of the campus. The plant capacity is a nominal 7,150 Tons supplying a primary loop

of 13,104 gpm and a secondary loop of 12,600 gpm. The points of connection for the Amini Center are a 12" chilled water supply (CHWS) and a 12" chilled water return (CHWR) lines located at the South end of the building.

#### Building Cooling System

Like the heating system for the building, the CHWS & CHWR lines enter/leave the facility in the mechanical room on the first floor. According to the designers load calculations, only 6" CHWS & CHWR lines were necessary to serve the Amini Center. The chilled water entering the building is supplied at  $42^{\circ}F$ .

Two pumps located in the first floor mechanical room provide circulation of the chilled water to the AHU and FCU cooling coils throughout the building.

Refer to page 2 of Appendix B for the Chilled Water Flow Diagram. Refer to Appendix C for available schedules of the heating equipment.

#### Air Distribution Systems

#### <u>AHU-1</u>

AHU-1 is a 23 Ton constant volume (CV) unit serving the 2,500 ft<sup>2</sup> Stem Cell Lab and supporting spaces on the first floor. This AHU is designed to supply 8,200 cfm of air to the space through 2x4 ceiling diffusers with HEPA filters. AHU-1 does not contain a HW heating coil in the unit. All heating for this unit is done through 6 HW duct mounted reheat coils. These reheat coils provide temperature control and zoning for the CV unit.

#### <u>AHU-2</u>

AHU-2 is a 38 Ton variable air volume (VAV) unit serving the 1,700 ft<sup>2</sup> Cryogen Freezer room and the 5,300 ft<sup>2</sup> Blood Processing Area on the first floor. This AHU is designed to supply 14,800 cfm through a mixture of CV and VAV terminals. The unit is designed with a pre-heat/main heating HW coil in the unit. Zoning is dictated by the terminal units which also have HW reheat coils. VAV terminal units have a minimum flow of 30% design air.

#### <u>AHU-3</u>

AHU-3 is a 63 Ton VAV unit serving 7,200  $\text{ft}^2$  of office and misc. space on the 1<sup>st</sup> floor and 16,700  $\text{ft}^2$  of patient bays, offices, and other misc. spaces on the 2<sup>nd</sup> floor. This AHU is designed to supply 26,900 cfm through VAV terminals with reheat. The unit is not designed with a heating coil in the unit. The VAV terminal units have a minimum flow of 30% design air and provide the only heating through HW reheat coils.

#### **FCUs**

All of the FCUs throughout this facility are horizontal units mounted in the ceiling plenums. These units serve areas with special cooling requirements, like 24/7 cooling for IT rooms. All FCUs have a chilled water coil but no heating coils, therefore these units are used for cooling only. Because these units serve interior spaces and are provided no OA, with the exception of 1 FCU, the heat loss should not be too significant to warrant heating coils. Without any design information for these special areas the loads will have to be assumed to meet what is shown on the schedule. The one FCU that does get OA, FCU-5-1, receives it to maintain the pressure relationship in the Mechanical Pump room.

#### Exhaust Air Systems

Exhaust air systems are usually added to a design to help with indoor air quality by removing foul or harmful odors/contaminants in the air streams. The Amini Center is no exception; it was designed with 5 exhaust fans that perform different functions. All the exhaust fans for this project are upblast fans grouped near each other and located on the roof, with the exception of EF-5 which is an inline fan located next to the Mechanical Room on the first floor.

#### <u>EF-1</u>

EF-1 serves five(5) Bio-safety cabinets located in the Stem Cell Lab on the first floor. These cabinets are the locations where potentially harmful bacteria or contaminants can grow in high concentrations while being tested/observed. For this reason, these areas need the air exhausted to the outside to dilute the concentrations.

#### <u>EF-2</u>

EF-2 serves the Cryo Freezer room on the 1<sup>st</sup> floor. This fan exhausts air from the room to maintain a negative pressure in that room.

#### <u>EF-3 & EF-4</u>

EF-3 and EF-4 are two general exhaust fans that serve bathrooms and soiled storage rooms.

#### <u>EF-5</u>

EF-5 is an exhaust fan for the pump room. Because the exhaust intakes are located above the steam pressure reducing stations, I believe this fan trying to reject heat from these pieces of equipment. No information was obtained regarding the design requirements for this fan.

#### **Control Features**

Controls and sequences of operation play a large role in the overall scheme to achieving energy savings, occupant comfort, and proper IAQ. Some of the control features for the Amini Medical Center can be seen below.

#### **General Control Features**

The building is equipped with automated DDC system.

The following pieces of equipment are provided with variable frequency drives (VFDs):

	VARIABLE FREQUENCY DRIVE SCHEDULE										
SYMBOL	LOCATION	SERVICE EMERGENCY		REMARKS							
VFD-1	ROOFTOP	AHU-1	YES	PROVIDE BYPASS							
VFD-2	ROOFTOP	AHU-2	YES	PROVIDE BYPASS							
VFD-3	ROOFTOP	AHU-2	YES	PROVIDE BYPASS							
VFD-4	ROOFTOP	AHU-2	YES	PROVIDE BYPASS							
VFD-5	ROOFTOP	AHU-2	YES	PROVIDE BYPASS							
VFD-6	ROOFTOP	AHU-3	YES	PROVIDE BYPASS							
VFD-7	ROOFTOP	AHU-3	YES	PROVIDE BYPASS							
VFD-8	ROOFTOP	EF-1	YES	PROVIDE BYPASS							
VFD-9	ROOFTOP	EF-2A	YES	PROVIDE BYPASS							
VFD-10	ROOFTOP	EF-2B	YES	PROVIDE BYPASS							

VFD-11	ROOFTOP	EF-3	YES	PROVIDE BYPASS
VFD-12	ROOFTOP	EF-4	YES	PROVIDE BYPASS
VFD-13	183 MECH PUMP	P-1	YES	PROVIDE BYPASS
VFD-14	183 MECH PUMP	P-2	YES	PROVIDE BYPASS
VFD-15	ROOFTOP	HTP-1	YES	PROVIDE BYPASS
VFD-16	ROOFTOP	HTP-1	YES	PROVIDE BYPASS

The following units and exhaust fans are interlocked with each other to maintain the proper pressure relationships in the rooms they are associated with:

- AHU-1 is interlocked with EF-1
- AHU-2 is interlocked with EF-2
- AHU-3 is interlocked with EF-3 & EF-4
- FCU-1-5 is interlocked with EF-5

Due to the VFDs on the chilled water pumps and the HTP pumps, 2-way valves are provided on the cooling and heating coils to take advantage of pump savings when possible.

#### Sequences of Operation

To aid in the understanding of the sequence of operations for these units, refer to Appendix D for unit diagrams.

#### AHU-1

Unit shall operate 24/7, but can start and stop on call from DDC. Upon start (EF-1 to start also), OA/RA dampers open to setpoint and fan is energized. Supply airflow station modulates supply fan (SF) VFD to maintain cfm setpoint. Cooling coil valve modulates as necessary to maintain 54°F. OA measuring station shall modulate OA/RA dampers to maintain air quantities. Upon shutdown, the fan shall stop then the OA dampers close.

#### EF-1

EF-1 shall start when AHU-1 starts. Airflow measuring station shall control fan VFD to exhaust set airflow quantity. EF-1 shall stop running shortly after AHU-1 supply fan shuts down.

#### AHU-2

Unit shall operate 24/7, but can start and stop on call from DDC (EF-2 shall start and stop when AHU-2 does). When unit is operating correctly, dual supply fans and dual exhaust fans are running simultaneously (at part load). Reheat coil and cooling coil valves shall modulate to maintain a supply air temperature of 54°F. Static pressure sensors, one at blood processing and one at Cryo freezer, shall modulate the supply fans VFDs to maintain setpoint. The units exhaust fan VFDs shall modulate accordingly with the SFs. Minimum OA setpoint shall be used when unit is above 65°F. When OA drops below 65°F, OA dampers can modulate up to 100% OA (RA dampers would simultaneously modulate down to 0%) as long as the preheat valve remains closed (Economizer Mode).

Upon failure one supply fan, or one exhaust fan, its associated EF/SF shall shut down and a damper shall isolate these fans to receive no airflow. The working SF/EF pair shall ramp up to maximum capacity, OA damper shall modulate to setpoint also, and VFD for the SF shall maintain the Cryo Freezer sensor's static pressure only. All other operations shall remain the same as when the unit is operating correctly.

#### EF-2

EF-2 shall start when AHU-2 starts. EF-2 shall stop running shortly after AHU-2 supply fan shuts down. EF-2 contains (2) fans, if one does not start or fails, the other shall energize.

#### AHU-3

Unit shall operate by a schedule and is started and stopped through the DDC system. On startup, OA/RA dampers shall open to fixed position then fan shall start. Upon shut down CHW valves shall close and fan shall run for another 5 mins. After that time, the fan shall shut down and then the OA dampers to close. EF-3 & EF-4 shall operate when AHU-3 is scheduled to operate.

For morning warm up the unit shall keep the OA dampers closed when the OA temperature is greater then 55°F. The supply fan (SF) and return fan (RF) shall energize and the cooling coil valve shall modulate to maintain 54°F supply air. If OA temperature is 55°F or less, economizer mode shall be initiated and the mixed air damper and outdoor air dampers shall modulate to maintain a mixed air temperature of 60°F with a low limit OA temperature of 45°F.

In occupied mode the minimum OA damper shall open to its setpoint. Above 55°F and below 45°F the other OA damper shall remain closed. Between 45°F-55°F OA temperature, the OA/MA damper shall modulate to maintain 60°F mixed air temperature. Cooling coil valve shall modulate to maintain 54°F supply air.

Rooms with  $CO_2$  sensors shall first increase the airflow available from the air terminal serving it before an increase in outside air is provided. Outside air damper shall slowly modulate open (decreasing the mixed air) until the required ventilation air quantities are provided.

#### EF-3 & EF-4

EFs 3&4 shall start operate when AHU-3 operates. VFDs shall be used for air balancing. EFs 3&4 shall stop running shortly after AHU-3 supply fan shuts down.

#### Reheat Coils

Space thermostat shall modulate reheat coil valve to maintain temperature setpoint.

#### Constant Volume Terminal Units

Air velocity sensor shall modulate damper to maintain cfm setpoint. Space thermostat shall modulate reheat coil valve to maintain temperature setpoint. Zone being served shall be provided with occupied and unoccupied schedule.

#### Variable Air Volume Terminal Units

Space thermostat shall modulate the VAV damper or reheat coil valve to maintain temperature setpoint. If VAV damper has reached minimum cfm setpoint, reheat valve shall then modulate to maintain temperature setpoint. Zone being served shall be provided with occupied and unoccupied schedule.

Air terminals serving rooms with  $CO_2$  sensors shall increase air quantity on VAV unit, thermostat to modulate reheat valve, until  $CO_2$  reading are acceptable. If continued  $CO_2$  concentration, air handling unit shall gradually increase OA until  $CO_2$  levels are met.

#### Fan Coil Units (FCU)

Space thermostat shall energize supply fan modulate cooling coil valve to maintain temperature setpoint.

FCU-1-5 is provided with two thermostats in two separate rooms it serves. The higher recorded temperature is the controlling point for the unit cooling setpoint. EF-5 shall operate when FCU-1-5 operates.

#### EF-5

EF-5 shall start when FCU-1-5 starts. EF-2 shall stop running shortly after FCU-5-1 supply fan shuts down.

#### Steam Pressure Monitoring

The DDC controls system shall record the steam flow rate measured by the flow meter. The DDC system shall interface with the mass flow meter for energy monitoring.

#### Heat Transfer Package

The DDC shall monitor hot water supply (HWS) and return temperatures. Alarm shall be sent to if HWS falls below 160°F.

#### Chilled Water Plant/Pumps

On a call for cooling by any one of the air distribution systems, the chilled water valve shall open and both pumps shall energize. Pump VFDs shall modulate to maintain differential pressure setpoint. Upon failure of one pump, the other shall operate to maintain necessary setpoint.

Building CHWS and CHWR temperatures shall be monitored. If the differential temperature is above the setpoint by 15°F, then the chilled water bypass valve shall open. If the differential temperature setpoint is 9°F or less, then the chilled water bypass valve shall close.

## Lost Rentable Space

Due to the world growing and expanding, land has become harder to come by, especially in large cities. Building owners therefore want as much rentable/useable space inside their building as possible. Obviously a building cannot operate without mechanical and electrical systems, but these systems take up rentable space. For the Amini Center, the lost rentable space to mechanical and electrical systems can be seen in the following table. These values do not incorporate janitor closets, elevator machine rooms, IT rooms, etc.; just mechanical and electrical spaces & chases.

Amini Center Lost Rentable Space								
Floor	Space Type	Area (ft <sup>2</sup> )						
1st	Mechanical	500						
1st	Electrical	600						
1st	Chase	30						
2nd	Mechanical	0						
2nd	Electrical	100						
2nd	Chase	205						
3rd	Mechanical	0						
3rd	Electrical	-						

3rd	Chase	205
	Total	1640
	% of Total Area	3%

Because the majority of the equipment was located on the roof, the owner did not lose a large amount of real estate for this building. Much of the space for the mechanical systems is needed in the ceiling plenum. The floor to floor heights of this facility are about 15 ft to accommodate the mechanical systems.

## Mechanical Systems First Cost

The overall cost to install and activate the mechanical systems, excluding Electrical hook-up, was estimated to be \$2.8 million. This price was taken from a total cost estimation prepared by DPR Construction Inc. Refer to Appendix D for the breakdown of DPR's estimation.

## Load and Energy Results

Load and energy calculations were performed for the Amini Center in Technical Assignment 2. Because this evaluation required a more in depth review of the mechanical systems, this section will provide an overview of the Tech. Assignment 2 results and discuss them further.

#### Load Results Overview

In Tech. Assignment 2 the building loads were simulated using the TraneTrace700 program. Weather data, internal loads, ventilation loads, solar loads and other data was input into the program based on the design documents. Lighting and equipment loads for assignment 2 were input on a W/SF basis, and the ventilation loads were locked in place with the scheduled values. For spaces with no equipment was given, i.e. elev. mach. rm. & IT rooms, equipment loads were taken from the designers EnergyPro model. The cooling loads scheduled and the calculated loads are summarized below.

	Trace Program		Design Documents			Trace Program		Design Documents	
Unit	Total	Sensible	Total	Sensible	Unit	Total	Sensible	Total	Sensible
	MBH	н мвн мвн мвн			MBH	MBH	MBH	MBH	
AHU-1	259.0	145.5	277.6	264.0	AHU-2	392.5	319.9	453.8	440.1
AHU-3	608.3	525.0	751.0	680.6	FCU-1-1	5.0	4.9	10.8	6.2
FCU-1-2	15.1	15.1	47.3	38.3	FCU-1-3	45.2	45.2	100.4	55.2
FCU-1-4	7.6	7.5	17.4	10.4	FCU-1-5	132.1	97.5	91.1	82.9
FCU-2-1	49.4	49.4	72.4	58.6	FCU-2-2	17.3	17.3	3.5	2.8
FCU-2-3	9.3	9.3	3.5	2.8	FCU-2-4	10.4	10.4	8.1	6.5

#### **Energy Results Overview**

Also Tech. Assignment 2, the building's energy usage was simulated using the TraneTrace700 program. For this simulation, fan energies, equipment efficiencies, usage schedules, occupancy schedules, cooling/heating plant information, and other factors were input to simulate how the building would operate over the span of one year. The results for the Amini Center's energy usage are summarized below.

Amini Center Annual Energy Consumption										
	Elec Consumption (kwh)	Purchased Chilled Water (kBtu)	Purchased Steam (kBtu)	% Total Energy	Total Building Energy (kBtu/yr)	Total Source Energy (kBtu/yr)				
Primary Htg			26,204	0.54	26,204	34,939				
Other Htg Accessories	249			0.02	849	2,548				
Primary Cooling		2,233,676		46.07	2,233,676	1,718,212

To put a dollar amount on the energy usage, a utility rate schedule needed to specified. Because the building is served from a central plant, district chilled water and district steam were simulated with no cost to the building. The only cost incurred by the building was calculated for the electricity used to run the air distribution systems, chilled water pumps, HTP, and the lighting and plug loads of the building. The schedule used for the electricity rate was taken from Southern California Electric website. This rate structure can be viewed below.

Amini Center	Input Rate Structure		
Utility	Customer Charg	e	Rate
Electric Demand			
On Peak (Jan. – Dec.)	224 EE ¢/mon	24.9	95 \$/KW
Mid Peak (Jan. – Dec.)	334.35 \$/1101	2.5	58 \$/KW
Electric Consumption			
On Peak (Oct. – May)	-	0.078	82 \$/kwh
Off Peak (Oct. – May)	-	0.05	56 \$/kwh
Mid Peak (Oct. – May)	-	0.078	82 \$/kwh
On Peak (Jun Sept.)	-	0.12	29 \$/kwh
Off Peak (Jun Sept.)	-	0.05	53 \$/kwh
Mid Peak (Jun Sept.)	-	0.069	94 \$/kwh

\* Rates are based on SCE rate schedule

This structure coupled with a time of day schedule designating On, Off & Mid peak produces the means to provide a dollar amount for the Amini Center's energy usage. A summary of the facility's cost breakdown is below.

Amini Utility Co	sts
Electric	\$/yr
On Peak Cons.	\$9,327
Off Peak Cons.	\$15,425
Mid Peak Cons.	\$31,142
On Peak Demand	\$48,321
Mid Peak Demand	\$8,993
Total:	\$113,208
Total \$/ft <sup>2</sup>	\$3.26

#### Discussion

Because construction of this building is scheduled to be complete in February, 2009, no information concerning energy usage and billing exist. The following discussion will therefore not evaluate any billing differences but discuss aspects of the model and its believed accuracy.

#### Loads

Loads for any building are subject to estimation and interpolation and the Amini Center is no different. I believe the solar loads and the wall loads calculated by the program are great estimations for the building's performance; as long as the envelope was input correctly. For the internal loads, however, a designer makes estimations for the heat produced in the space based on equipment, people activity, ventilation requirements, and other factors. Many pieces of equipment can be referenced for heat loads, but not all equipment is listed. In the case for this complex, many areas like the labs and research areas contain pieces of equipment which can not be looked up, making it hard to estimate the heat loads without going to the manufacturers. I believe this is the main discrepancy for the differences in loads observed by Tech. Assignment 2 and those scheduled. Another discrepancy that factors into the load differences was the fact that the owner wanted there to by 15% extra capacity on all the AHUs.

Some minor factors I believe to affect the loads include slight differences in weather data, people loads, and lighting loads. These factors will also change the load calculations, but no where near the extent of the previously mentioned factors.

The loads for the FCUs seem to be marginally different from scheduled loads. Considering these W/SF loads were taken from the designer's energy model, I initially thought they were accurate. After further investigation I feel the loads were input wrong or changed by the design team, creating inaccurate loads from what is scheduled.

#### <u>Energy</u>

The energy results from Tech. Assignment 2 were hard for me to judge because I'm not aware of typical energy costs for a clinical building in the LA area. After a more in depth review of the Amini Center's mechanical systems, I do believe the numbers calculated in Assignment 2 are low compared to what the building will actually see. I feel the building was not correctly modeled with the proper control schemes and loads.

In Assignment 2, the AHUs and EFs were input based on building occupancy schedule, not based on loads. Considering both AHU-1 and AHU-2 are operating 24/7, the energy usage will be greatly different. Other factors that were not incorporated into the model include the rooms with  $CO_2$  sensors and the demand limiting ventilation applied to AHU-3. Other design conditions that might affect the cost include design conditions like oversized units, ventilation requirements, and also the facility's need for positively and negatively pressured rooms.

The last energy issue with the Amini Center is the fact that the numbers given in this evaluation apply only to the first and second floor units. The third floor, future units, were not accounted for.

## System Critique

Because the Amini Medical Center is an addition to an already existing campus, it appeared to be a simple choice for the engineer on how the building would be heated and cooled. Having existing chilled water and steam lines gave the designer excellent resources to design an efficient building.

#### **Central Plant**

Because there is little known about the central heating plant, there is no room to discuss its design. For a campus facility like this one, I do believe a high pressure steam system provides benefits for the buildings on campus.

The central water cooled chiller plant is also believed to have benefits for a campus community. Not knowing how the chillers are piped (series or parallel) and the control sequencing for them does not allow any critique based on energy consumption.

#### **Building Equipment**

For this facility, having the water cooled AHUs on the roof, took up minimal floor area for the tenant. It did however increase the plenum size to allow the necessary duct runs and equipment, there by increasing the overall height of the building.

The specific requirements for the spaces seem to be met very well with the system that has been provided. The temperature control seems to be accounted for with reheat coils on the CV system and the terminal units on the VAV systems. All two way valves were used to gain energy savings on the pumps with VFDs.

One issue I had with the system resulted from the controls of AHU-1. The VFDs on AHU-1 and EF-1 seemed unnecessary to me because it is a constant volume system. I don't know why these features were added, but it might be a design requirement for the lab it serves.

Another interesting design feature was the dual fan system for AHU-2. This feature was obviously added to provide the Cryo freezer with redundancy, but it seemed out of the ordinary. It had me curious if there was another way to provide redundancy for that space; most likely not without increasing first cost significantly.

Overall I believe the system is a very good design which seems to meet the requirements of the owner and also provides energy efficient strategies.
