Executive Summary

The goals of this report are to research and design three alternative floor framing systems for the University Academic Center and compare these systems along with the as-built system to determine overall feasibility. This was accomplished through analysis with current codes and standards, design catalogs, and computer analysis software.

The existing composite flooring system was analyzed in a typical 32’-8”x30’ bay located in the central classroom wing, being the most common bay layout in the building. The analysis confirmed the use of a 2VLI18 deck type as specified in Vulcraft deck catalog equating to a 2” 18 gage composite deck with 3-1/4” LWC topping. The use of W18x40 beams with 24 studs and W21x73 girders with 34 studs was also confirmed. Computer analysis was also done in RAM to double check the beam/girder sizes. This system resulted in an overall depth of 26.25”, and cost of $20.91 plus cambering estimated at $30 per member.

Alternative 1 was a non-composite system. Calculations resulted in an increase to 3” 20 gage non-composite deck with 4-1/2” LWC topping. Beam and girder sizes also increased to W18x55 and W24x68 respectively. This system resulted in an overall depth of 31.5”, cost of $23.03, and a 134% original load applied to the foundations. The non-composite system was considered feasible for future design.

Alternative 2 was a precast concrete hollow core plank flooring system supported by steel beams. Design data for the hollow core planks came from Nitterhouse Concrete Products. To incorporate the planks the layout had to be altered to a 32’x30’. Design resulted in 10”x4’ planks 30’ in length with a 2” topping. A beam size of W27x94 was used to support the planks. This system resulted in an overall depth of 39”, cost of $18.95, and a 199% original load applied to the foundation. The hollow core plank system was considered unsuitable for future investigation.

Alternative 3 was a two-way flat slab floor system with drop panels. Thickness of slab was chosen at 11” based on code minimum slab thickness. Drop panel dimensions were also determined to be 11’x10’ based on ACI 318 code limitations and punching shear calculations. The remainder of the design was determined using spSlab. This system resulted in an overall depth of 15”, cost of $17.72 and a 297% original load applied to the foundations. A two-way slab system was considered a possibly feasible alternative floor system.
Introduction

Located in the eastern United States, the University Academic Center is a 192,000 square foot building designed to house a library resource center, dining area, 45 classrooms, and over 120 offices. Other key features include a 5-story atrium and multiple roof gardens.

The layout of the building consists of three main sections. The northern 3-story section contains mostly dining and classroom areas. In the center of the building, a 4 story section houses the library and the majority of classrooms, as well as acting as the main entrance. The southern end of the building consists almost entirely of office spaces. On either side of the center section are the vertical circulation cores which also provide access to the roof gardens.

There are 4 main types of building façade implemented in this building. The 3 and 5-story sections of the building have a brick façade with cast stone bands running horizontally across the brick surface. Glass curtain walls are used in the vertical circulation located on either side of the 4-story section. The 4-story section's façade is mostly metal panels. There is also glazed CMU used to accent the other façade types at various places.

Through the use of multiple energy saving techniques the University Academic Center holds a LEED gold rating. This includes energy efficient HVAC equipment and the use of natural daylighting, as well as shading devices, to help minimize energy consumption. All these features, along with the roof gardens, provide a “green” learning environment. LEED credits were also gained through site design to minimize storm water runoff, use of recyclable and local materials, and the addition of bike racks and on site showering facilities to promote alternative modes of transportation.
Structural Overview

The University Academic Center is a steel framed building with composite metal decking supported by a foundation of spread footings and slab-on-grade. The building resists lateral forces by a combination of braced and moment frames.

Foundation

Based on the 2002 geotechnical report taken, footings for University Academic Center are designed for an allowable bearing capacity of 3000 psf. Footings are placed on undisturbed soil or on structurally compacted fill. The bottoms of exterior footings are 2’-6” below grade.

Slab-on-grade sits on a coarse granular fill material compacted to 95% of maximum density as defined by ASTM D1557 modified proctor test. The slab-on-grade is designed as 5” thick concrete reinforced with 6”x6”, W1.4xW1.4 WWF. This is the reinforcement for all slab-on-grade except for the area located under the library stacks which is 6” thick concrete reinforced with 2 layers of 6”x6”, W2.1xW2.1 WWF.

Drawings provided by Skanska
The columns in the University Academic Center sit on piers ranging in size depending on loading and connection type. The columns are embedded 8” in concrete then anchored to a base plate which sits on the pier. These piers are a minimum of 8” ranging to a maximum depth of 3’-9”. The piers come in 4 types: 4, 6, 8, and 12 vertical bar piers. Footings also range in size under the columns with a maximum 19’x19’ under a single column.
Floor and Roof Systems

The University Academic Center utilizes a composite metal deck flooring system. This includes 2” composite 20 gage deck with ribs 12” o.c. and 1.5” type B, wide rib 20 gage deck. All metal deck is designed to be continuous over 3 spans. Floor system also includes shear studs and lightweight concrete topping varying based on location and loading.

Roofing systems also vary due to some areas like the roof gardens and mechanical spaces of greater loading. Decking for roofs includes both 2” composite 18 gage deck with ribs 12” o.c. and 1.5” type B, wide rib 20 gage deck, covered by a built up roof and rigid insulation.
**Framing System**

The framing system for the University Academic Center includes C-shapes, HSS members, and Wide Flange members with the majority being W-shapes. Gridlines are set at multiple angles with bay sizes varying throughout the building. Areas with consistent framing between floors are located in the classroom wing in the central section of the building and the office spaces on the south side.

**Lateral System**

The lateral system for this building includes braced frames of varying heights and types located throughout the building. To the right is a plan view of University Academic Center with the 15 lateral braced frames shown in blue.

- ACI 318-11
- Nitterhouse load tables
- Vulcraft deck catalog
- spSlab
- RAM
- RS Means Costworks data
Design Loads

Dead Loads

Dead loads are estimated based off material weights found in the AISC Steel Construction Manual since no values were given on drawings except for weights of rooftop units which range from 8,000-45,000 lbs. Deck weight is compared to similar weights in Vulcraft catalog based on topping thickness and deck type.

Live loads

Live load values were given on the drawings. These values are shown along with the values given in ASCE7-10 in the table below. Where values are not given in one source the value from the other source was used in calculations. Likewise, when differing values are present the larger of the two was used in thesis calculations.

**Alternative Floor Systems:**

Many factors go into a designer's choice of building materials and layouts such as weight, cost, floor to floor heights, spans, deflections, and foundation considerations to name a few. When comparing alternative flooring systems these factors were weighed to determine feasibility. This report will compare the existing system and 3 alternative systems which include:

- Composite deck on composite steel beams and girders
- Non-composite deck on steel beams and girders
- Precast concrete hollowcore planks on steel beams
- Two-way slab with drop panels

Below is the 32’-8”x30’ typical bay chosen for comparison purposes.
Composite Floor System

Advantages

Composite systems use the concrete in the deck to take compression loads while the steel takes the tension loads, this combined effort allows for smaller member sizes reducing weight and depth as well as deflections. The efficiency of composite systems also allow for increased bay sizes maximizing space usage. As with all steel systems, the composite system is lighter than a concrete system allowing for smaller foundations. Composite systems also have the option of cambering members, which is utilized in the University Academic Center, in order to further reduce deflections.

Disadvantages

A composite system can be costly with a higher level of difficulty in construction than other systems. This is because all the things that make composite more efficient cost money to employ such as cambering beams and installing shear studs. All steel systems including composite must also be fireproofed and are typically hidden from view with a drop ceiling.

Analysis

The current composite system was analyzed using both hand calculations and RAM software to verify that member sizes pass all requirements, this can be found in Appendix A. This system resulted in an overall depth of 26.25” and a self weight of 48.23 psf. The system used cambering to keep deflections within limits but this also adds cost, about $30 per beam according to Erine Criste’s article in STRUCTURE magazine, making the real cost per square foot higher than the one calculated from RS Means Costwork of $20.91. University Academic Center uses a drop ceiling to hide the composite system which must be fireproofed also adding cost.
Non-composite Floor System

Advantages

A non-composite system is a cheaper, faster, and less labor intensive alternative to the composite system. There are no shear studs to weld to members and therefore less opportunity for mistakes during installation. Non-composite systems share the weight advantages of a composite system as well as the reduction of space usage.

Disadvantages

Non-composite systems share some composite system disadvantages including the need for fireproofing and drop ceilings. They also are more prone to deflection and vibration issues due to their relatively flexible frames. The main disadvantage of a non-composite system is the reduced amount of strength when compared to composite systems. The inability to maximize the concrete’s strength through composite action results in concrete simply acting as a load for the steel to bear. This results in larger and heavier members than those used in composite systems.

Analysis

The non-composite design uses the same bay layout as the existing composite system making comparisons more precise. Since a non-composite system does not use the concrete in the deck to take loads in flexure member sizes increased from W18x40 and W21x73 to W18x55 and W24x68. This increase in member size also increases overall depth to 31.5” and self weight to 64.58 psf.

The non-composite system is slightly worse than the existing system in weight, depth, and deflection but when the lower price of $23.03 per square foot and the ease of construction are factored in, this system may be considered feasible for redesign.
Precast Hollowcore Plank System

Advantages

Hollowcore planks provide a high level of consistancy as far as strength since they are pre-made. They also eliminate the waiting time to cure and allow for less time spent during construction and a easier construction. Hollowcore planks can eliminate the need for drop ceilings and, if coordinated properly, allow for MEP equipment to be installed in the voids in the planks keeping them out of sight. Hollowcore planks are also capable of spanning large distances increasing bay sizes and usable floor space.

Disadvantages

Although the planks themselves do not require fireproofing the steel beams supporting them will. These beams will also increase system depth and most likely utilize drop ceilings making system depth a major disadvantage to a hollowcore plank design. The pre-made planks also result in limited options regarding layouts making this system more favored to rectilinear designs than complex geometries.
Analysis

Hollowcore planks were chosen from Nitterhouse Concrete Products. Based on their load tables and the loading in a typical classroom bay, a 10” plank with 2” topping for fire protection was chosen. Because of the modular size of 4’ wide planks the bay size was slightly changed to 32’x30’. To support the planks a W27x94 girder was needed. This would put the overall depth at 39”, the largest of the 4 systems, and the self weight at 95.94 psf, most likely requiring some sort of foundation redesign. Using RS Means Costworks data the price of a hollowcore system was estimated at $18.95 per square foot.

Hollowcore planks are cheaper, easier, and faster to install than the existing system. They also provide the option to incorporate MEP systems within the floor, but the added weight and depth of this system along with its inflexible layout options make hollowcore planks an undesirable option for the University Academic Center.

Two-way Slab with Drop Panels

Advantages

Using a concrete system like a two-way slab offers many advantages over steel systems. Concrete is a cheap, continuous type of construction. It also acts as a natural fireproofing provided efficient clear cover and can be finished possibly eliminating the addition of drop ceilings. Two-way slabs with drop panels offer a unique advantage in that overall depth is significantly reduced allowing ample room for MEP needs and providing more options for floor heights. The added mass also reduces deflection and vibration concerns.

Disadvantages

One major disadvantage to a two-way slab is the added weight putting a larger stress on the foundation system most likely resulting in a redesign to handle the new loads. Other disadvantages include the time required to cure concrete, the cost of formwork, and the placing of rebar.
Analysis

Design of the two-way slab with drop panels was done using spSlab, however first minimum slab depth and drop panel dimensions were calculated by hand using ACI 318-11 limits. It was determined that a slab thickness of 11” should be used and drop panel dimensions of 11’x10’ with a thickness of 15” were needed to resist punching shear. Results from spSlab showed deflections far lower than all other systems averaging around 0.1 inch. Reinforcement, deflection, and layout diagrams can be found along with initial calculations in Appendix D. This system came out to be the heaviest by far at 143.23 psf self weight, putting almost 300% loading on the foundation. Price was estimated at $17.72 per square foot using the closest assembly in RS Means Costworks.

The two-way slab system has the most weight requiring a foundation redesign, as well as difficult and lengthy construction compared to the other systems. However, two-way slabs offer many advantages the steel systems do not including the lowest overall depth, best deflection/vibration control, and built in fireproofing with the possibility of eliminating drop ceilings. This along with the lowest estimated price, makes a two-way slab with drop panels a feasible alternative flooring system for the University Academic Center.
# System Comparison

The table below shows a comparison of the 3 alternative systems compared to the existing composite system. Positive aspects when compared to the original system are shown in green while negative aspects are shown in red.

Conclusion

Based on the study of the existing system and the advantages and disadvantages offered by each of the 3 alternative systems it has been concluded that all systems except for the precast hollowcore planks can be considered for future study.

The existing composite system offered efficiency in its use of space and strength. A non-composite system, while not as strong as a composite system, required increased member sizes, but offered a cheaper and easier construction to keep it a feasible option. The two-way slab system offered a completely different type of appeal being the most efficient as far as price, depth, and stiffness were concerned. However it was the heaviest system causing foundation concerns. It still had enough positive aspects to make it worth further investigation.

The only system that was considered too impractical was the precast hollowcore plank system. This system still offered long spans and was reasonably priced, but this system has both the undesirable depth of a steel system with the weight of a concrete one. This along with the limitations in layout due to the modular sized planks make a hollowcore system an unviable flooring option for University Academic Center.

Appendix B: Non-composite Calculations

Alternative 1: Non-Composite

Deck Design:

- **LL**: 50 psf + 15 psf (artifacts) = 65 psf
- **DL**: 10 psf (summarized DL) + 5 psf (MEP) = 15 psf
- **TL**: 80 psf

**TRY 3C carbon decking**

- **REK**: 10’ span = 10’
- **TRY**: 7.5” thickness, 4.5” topping → 4x4 W2.9 x W2.9

allowable load = 134 psf > 80 psf

- **7.5” x 4.5” topping**: 3’ span = 12’-2” > 10’
- **TRY 3C20**: weight = 57 psf

3C20 → 1/80 allowable uniform load = 119 psf > 110 psf

→ 1/80 allowable uniform load = 152 psf > TL = 80 + 57 = 137 psf

**USE 3C20 non-composite deck 4.5” (LWC topping) 7.5” thick**

w/ 4x4 W2.9 x W2.9 W/WF reinforcing
Bean Design:

\[ DL = 15 \text{ ft}^2 + 57 \text{ ft}^2 + 5 \text{ ft}^2 \cdot \left( \frac{\text{gal}\cdot\text{ft}}{\text{ft}^2} \right) = 77 \text{ ft}^2 \]

\[ UL = 65 \text{ ft}^2 \rightarrow UL \text{ reduction} \rightarrow UL = 54.4 \text{ ft}^2 \]

\[ W_u = 12 \cdot \left( \frac{1.77(10)}{10000} \right) + 1.4 \cdot \frac{64.9(10)}{10000} = 1.794 \text{ k} \]

\[ V_u = \frac{W_u}{\gamma} = \frac{1.794(12.47)}{2} = 29.3 \text{ k} \]

\[ M_u = \frac{W_u \cdot L^2}{8} = \frac{1.794(12.47)^2}{8} = 239.8 \text{ k}\cdot\text{ft} \]

TRY W18 x 40

\[ \# M_{pl} = 29.4 \text{ k}\cdot\text{ft} > M_u \text{ OK} \]

\[ \# V_u = 169 \text{ k} > V_u \text{ OK} \]

\[ I_x = 6.12 \text{ in}^4 \]

\[ w_{oc} = 72 + 54.7(10) - 40 = 1.304 \text{ k}\cdot\text{in} \]

\[ \Delta_{ul} = \frac{5(6.544)(32.67)(128)}{384(29000)(6.12)} = 0.786 \text{ in} \]

\[ \Delta_{allow} = \frac{w_{oc}}{200} = \frac{32.67(10)}{200} = 0.1637 \text{ in} < 0.786 \text{ in} \text{ OK} \]

\[ \Delta_{cl} = \frac{5(1304)(32.67)(128)}{384(29000)(6.12)} = 1.883 \text{ in} \]

\[ \Delta_{allow} = \frac{I_x}{240} = \frac{32.67(10)}{240} = 1.361 \text{ in} < 1.883 \text{ in} \times \text{Not Conft} \]

DESIGN DATA
1. Precast Strength @ 28 days = 6000 PSI
2. Precast Strength @ release = 3500 PSI
3. Precast Density = 150 PCF
4. Strand = 1/2"Ø and 0.6"Ø 270K Lo-Relaxation.
5. Strand Height = 1.75 in.
6. Ultimate moment capacity (when fully developed):
   - 6-1/2"Ø, 270K = 168.1 k-ft at 60% jacking force
   - 7-1/2"Ø, 270K = 191.7 k-ft at 60% jacking force
7. Maximum bottom tensile stress is $10\sqrt{f_c} = 775$ PSI
8. All superimposed load is treated as live load in the strength analysis of flexure and shear.
9. Flexural strength capacity is based on stress-strain strand relationships.
10. Deflection limits were not considered when determining allowable loads in this table.
11. Toppling Strength @ 29 days = 3600 PSI. Toppling Weight = 25 PSF.
12. These tables are based upon the toppling having a uniform 2" thickness over the entire span. A lesser thickness might occur if camber is not taken into account during design, thus reducing the load capacity.
13. Load values to the left of the solid line are controlled by ultimate shear strength.
14. Load values to the right are controlled by ultimate flexural strength or fire endurance limits.
15. Load values may be different for IBC 2000 & ACI 318-99. Load tables are available upon request.
16. Camber is inherent in all prestressed hollow core slabs and is a function of the amount of eccentric prestressing force needed to carry the superimposed design loads along with a number of other variables. Because prediction of camber is based on empirical formulas it is at best an estimate, with the actual camber usually higher than calculated values.

This table is for single spans and uniform loads. Design data for any of these span-load conditions is available on request. Individual designs may be furnished to satisfy unusual conditions of heavy loads, concentrated loads, cantilevers, flange or stem openings and narrow widths. The allowable loads shown in this table reflect a 2 Hour 8 9 minute fire resistance rating.
Appendix D: Two-way Slab Calculations and spSlab Results
Alternative 3: Two-way Slab

Determine drop panel dimensions thru punching shear:

\[ V_0 = 0.293 \left( \frac{32(30)}{2} - 4 \right) = 280.1 \text{ k} \]

\[ V_c = 43 - \frac{V_c}{V_0} \text{ k} \]

\[ \text{min dimension} \rightarrow h_c = \frac{32}{c} = 5 \text{ in} \]

\[ \frac{32}{c} \geq 5 \rightarrow \text{TRY } 11 \times 10 \text{ drop panel} \]

\[ 280.1 \text{ k} < 0.75(4)(1)\sqrt{33000(538)(8.5)} \]

\[ 280.1 \text{ k} < 751.4 \text{ k} \checkmark \]

\[ \text{USE } 11 \times 10 \text{ drop panel} \]

Assume drop panel \( h_d = 1.25 \times h_c = 13.75 \text{ in} \rightarrow \text{TRY } h_d = 14 \text{ in} \)

\[ f_{cu} = 1.2 \left( \frac{32}{c} \right)(50 \text{ psi}) = 45 \text{ psi} \]

\[ V_0 = 0.293 (32(30)-4) + 0.015 (10-4) = 284.9 \text{ k} \]

\[ b_1 = (12 + 20) = 144 \text{ in} \]

\[ V_c = 0.75 (4)(1) \sqrt{33000(144)(12)} = 283.9 \text{ k} \checkmark \]

\[ \text{TRY } h_d = 15 \text{ in} \]

\[ f_{cu} = 1.2 \left( \frac{32}{c} \right)(50 \text{ psi}) = 60 \text{ psi} \]

\[ V_0 = 0.293 (32(30)-4) + 0.06 (10-4) = 286.5 \text{ k} \]

\[ b_1 = (13 + 20) = 143 \text{ in} \]

\[ V_c = 0.75 (4)(1) \sqrt{33000(143)(13)} = 316.1 \text{ k} \checkmark \]

[**Note:** Using dimensions from floor system, design of reinforcement was done in spSlab]

Estimate for Composite and Non-composite systems

Estimate for Precast Hollowcore Plank system

Estimate for Two-way slab with drop panels
System Comparison | Tech 2 | Alexander Altemose

Composite

self-weight = 42 psf + 40 psf + 73 psf / 100 = 48.33 psf

Foundation Impact = None

cost = $18.49 - 8.99 + 11.91

cost = $20.91 + camber cost ($30 per beam)

Non-Composite

self-weight = 57 psf + 55 psf + 68 psf / 12 = 64.58 psf

Foundation Impact = 14.59 / 18.23 (100) = 79.9% load

cost = $18.49 - 8.99 + 13.88 - 0.35

cost = $23.03

Hallowcore Blank

self-weight = (68 + 25) psf + 44 psf / 32 = 95.44 psf

Foundation Impact = 95.44 / 93.23 (100) = 100% load

(cost of location of filters will change)

Two-way Slab w/ Drop Panel

self-weight = 14.59 / 12 (150 psf) + 11 / 12 (150 psf) / 30

(cost of location of filters will change)

Foundation Impact = 143.23 / 48.23 (100) = 297% load

cost = $17.72
