# TECHNICAL REPORT 2

Evaluation of Alternate Floor Systems Advisor: Heather Sustersic October 12, 2012

## EXECUTIVE SUMMARY

Technical Report 2 evaluates the existing composite floor system against the three most viable alternatives that could have been used in the design and construction of the American Art Museum (AAM). Criteria of cost, weight, depth, architectural and structural impacts, MEP coordination, serviceability, and construction considerations were analyzed to find a potential alternative system. Against the lightweight purlin-girder (non-composite), two-way flat slab with drop panels, and one-way with beams and girders, however, the existing steel-composite system proved to be the best such that no considered alternative could effectively replace the current design.

Each system was designed according to a standardized 20' 8" x 20' typical bay for flexural and shear strength, servicability, and constructability considerations (dictated by column lines E-F and 3-4; see S-105 in Appendix A). The loads considered are discussed in the loads section of the report and are found on the dead and live load schedules on drawing S-200.01 in Appendix A. After design, each system was analyzed for weight and cost by a detailed estimate using RS Means Facilities 2012 and compared on a per-square-foot basis.

AAM's architectural design (Figure 1) likely arose from the owner's desire to have an iconic signature With that understanding, Renzo Piano buildina. Building Workshop (RBPW) most likely established the building's form and function assuming the use of a steel-composite system. If concrete had been a consideration from the beginning, either the flat slab with drop panels or the one-way slab with beams would have been economical alternatives to the existing steel-composite frame system. The form of the building with its large, heavy cantilevers and supports in tension make a concrete frame difficult, if not impossible. Additionally, the large, open art gallery spaces on the upper floors require spans of up to 70', which would be difficult to achieve with concrete.

Figure 1: Rendering of the Building (SW Corner)

The lightweight steel purlin-girder floor system could have been used if that was the desired system. Other lightweight floor systems are all but impossible due to the fact that many manufacturers do not include the span/load combinations required for this building. The steel weight, number of connections, and low resistance to vibrations, however, make the floor system nearly twice as expensive as the existing steel-composite system, offsetting any savings gained from column sizing, which would likely become controlled by the lateral analysis.

Precast concrete systems were not considered for similar reasons as web joists: manufacturers do not include the required span/load combinations required for AAM. Also, post-tensioned floor systems were ignored because the significance of the strength of the tension strands would decrease the flexibility of the gallery spaces.

# TABLE OF CONTENTS

## NTRODUCTION

The American Art Museum (AAM) will serve as a replacement to the owner's current facility in New York City. Figure 2 shows AAM's new location in a vibrant district where aging warehouses, distribution centers, and food processing plants are being renovated and replaced by art galleries, shops, and offices. AAM will stand in place of several such warehouses, and will provide a magnificent new southern boundary to the city's recently renovated elevated park, which terminates on the eastern edge of the site.

Renzo Piano's approach to AAM's design and architecture blends a contemporary

Figure 2: Arial map showing urban location along river (www.maps.google.com)

architectural style with the historical development of the city. The large cooling towers and outdoor terraces that step back towards the river on the west trace their roots back to the industrial revolution and its local impact. These outdoor terraces will also provide views of the southern skyline and space for outdoor exhibits and tall sculptures while being protected from any wind by the higher portions of the building's west side. Alternately, the large cantilevers, insets, large open spaces, exposed structural steel, and modular stainless plate cladding show no attempt to camouflage AAM with the more historical surrounding buildings.

AAM's façade is comprised of the aforementioned steel plate, pre-cast concrete, and glazing using a standard module of 3'-4" (about 1m) (shown in Figure 3). While most of the façade components are broken at each story, the long steel plates stretch 60' on the southern wall from levels 2 to 6 and from 6 to 9.

This new facility is a multi-use building with gallery and administration space, two café/restaurants, art preservation and restoration spaces, a library, and a 170-seat theater. Public space including the theater, classrooms, restaurants, and galleries are located on the south half of the building on the ground level and levels 5 through 8. Mechanical, storage, conservation, offices, and administration are dispersed on the north side at each level. The 220,000 square-foot AAM will stand 148ft tall and cost approximately \$266 million. Construction began in May 2011 and is expected to be complete in December 2014.

## Structural Systems

### OVERVIEW

AAM sits on drilled concrete caissons encased in steel with diameters of either 9.875" or 13.375" capped by pile caps. From the foundation level at 32' below grade, 10 levels rise on steel columns and trusses. Each floor will be supported by a steel-composite system. The lateral system consists primarily of braced frames spanning several stories. At some levels however, the floor system uses HSS diagonal bracing between beams and girders to create a rigid diaphragm that also transfers the lateral loads between staggered bracing. Moment frames are used for localized stability purposes. While masonry is used in AAM it is used for fire rating purposes only.

The building classifies as Occupancy Category III. This is consistent with descriptions of "buildings where more than 300 people congregate in one area" and "buildings with a capacity greater than 500 for adult education facilities."

### Foundations

URS Corporation produced the geotechnical report in February 2011 to summarize the findings of several tests and studies performed between 2008 and 2010. They summarize that while much of the site is within the boundaries of original shoreline, a portion of the western side is situated on fillin from construction. They explain further that the portion that was formerly river has a lower bedrock elevation and higher groundwater. Due to the presence of organic soils and deep bedrock, URS suggested designing a deep foundation system and provided lateral response tests of 13.375" diameter caissons socketed into bedrock.

The engineers acted on the above suggestions and others. The caissons are specified with a 13.375" diameter of varying concrete fill and reinforcement to provide different strengths to remain consistent with URS Corp's lateral response tests. Low-capacity caissons (9.875" diameter) are individually embedded in the pressure slab, while typical and high-capacity caissons are placed in pile caps consisting of one or two caissons. The high-capacity caissons are always found in pairs and are located beneath areas of high live load or where cantilevers are supported. For a complete layout and caisson schedule, see FO-100 in Appendix A.

A pressure slab and the perimeter secant-pile walls operate in tandem to hold back hydrostatic loads created by the soil and groundwater below grade. The walls vary between 24" and 36" and are set on 6'-6" wall footers and caissons. These are isolated from the pressure slab. The cellar level floor slab consists of a 5" architectural slab-on-grade by a 19" layer of grave on top of a 24" pressure slab (Figure 5).

### GRAVITY SYSTEM

### FLOOR SYSTEM

A surprisingly regular floor layout contrasts the obscure geometry of the building (Figure 6). The engineers managed to create a grid with spacings of roughly 20' (E-W) and 30' (N-S), where the 20' sections are divided by beams which support the floor decking running E-W. Beams that do not align with the typical perpendicular grid indicate a change of building geometry below or above. Each beam is designed for composite bending with the floor slab.

Four slab/decking thicknesses are called for depending on deck span and loading, all on 3"-18 gauge composite metal deck. The most common callout is 6.25" (total thickness) lightweight concrete. This provides a 2-hour fire rating. 7.5" normal weight is used on level 1 for outdoor assembly spaces and the loading dock, and 9" normal weight is used for the theater floor. The roof above the level 9 5.5" mechanical space calls out composite.

While the layout can be considered relatively consistent, the beam sizes and spans selected suggest a much more complicated floor system. Though a typical bay spans 20'-30', the gallery floors

(levels 6-8) span over 70'. The shorter spans require filler beams as small as W14x26, but the longer spans supporting the upper gallery levels require beams as large as W40x297s for web openings. In several places welded plate girders are specified at depths from 32.5" to 72." The plate girders are used as transfer large loads and moments as propped cantilevers, especially from gravity trusses and lateral braced frames shown in Figure 7.

### FRAMING SYSTEM

Cantilevers on the south side of AAM are supported by 1 or 2-story trusses, typically running in the N-S direction. One large gravity truss runs along the southernmost column line between levels 5 and 6 to support the cantilever on the south-eastern corner of the building.

While the vast majority of columns are W12x or W14x shapes, some of the architecturally exposed steel vertical members are HSS shapes, pipes, or solid bars. Furthermore, the gravity load path goes up vertically and horizontally nearly as much as it flows directly down a column to the foundation. Figure 8 shows how large portions of the southern half of AAM's levels 3 and 4 are hung from trusses and beams on the level 5 framing system.

Renzo Piano's designs often expose structural steel, providing an extra constraint on the design team. One example is column 3-M.5 which supports level 5 from the outdoor plaza below. The foundation column below grade specifies a W14x311, a typical shape for a column, but the architecturally exposed structural steel is called out as 22" diameter solid bar. A unique analysis would be required for a solid bar acting as a column, as AISC XIII does not have provisions for such a selection in its tables or specifications.

### LATERAL SYSTEM

AAM's lateral system is as complicated as its gravity systems. Concentric braced frames stagger up the building, transferring lateral loads via diagonal bracing within the floor diaphragms on level 3 for the southern portion and 5 for the northern portion as shown in Figure 9. Most of the braced frames terminate at ground level, but three extend all the way down to the lowest level. Those braces that terminate at upper floors transfer uplift through columns that extend underneath them. Bracing members are comprised mostly of W10x, 12x, or 14x shapes in X-braces or diagonals. There are, however, HSS shapes are used with Kbraces. An enlarged floor framing plan showing the braced frames at level 5 is provided in Figure 10 below.

## Design Codes & Standards

The design codes listed for compliance of structural design can be inferred from drawing S-200.01 and Specification Section 014100.2.B:

- International Code Council, 2007 edition with local amendments including:
  - Building Code
    - Fire Code
- ASCE 7-05: Minimum Design Loads for Buildings and other Structures
- ACI 318 -08: Building Code Requirements for Structural Concrete (LRFD)
- AISC XIII: Specifications for Structural Steel Buildings (LRFD)
- AWS D1.1: American Welding Society Code for Welding in Building Construction

Other codes not applicable to the structural systems of the building can be found in the specifications.

### MATERIALS SPECIFICATIONS

The different materials specifications are summarized in Figure 11 below. Additional information can be found on drawing S-200.01 in Appendix A.

	Materials Specifications

# Building Gravity Loads

### LOADS SUMMARY

### Dead Loads

Because the live loads are so high, special care seems to have been taken by the design engineers to be very precise in their dead load calculations. Similar to the live loads, the diversity of different use types and load requirements have led to a congruent variety of dead load arrangements in structural steel weight, concrete density, MEP requirements, partitions, pavers, roofing, and other finishes. A total of 37 different dead load requirements, arranged by use and location, are listed in the Dead Load Schedule on drawing S-200.01 in Appendix A. These range from 76 PSF to 214 PSF. In all, the building has a dead weight of 23,084 k (11,500 tons) from level 1 through level 9 Roof North.

### Live Loads

Typically, one would expect to see Live Loads calculated from ASCE 7 minimums (ASCE 7 Table 4-1). The structural narrative explains that much of AAM does not fit with any ASCE 7 descriptions of use types, so the engineers have provided their own design loads summarized in Figure 12. Additionally the engineers created a live load plan on S-200.01 in Appendix A which shows areas of equal live load on each floor.

The engineers, in a desire for maximum flexibility of the gallery spaces, elected to conservatively design the AAM-specific spaces for live loads, while being consistent with ASCE 7 minimums for more common areas.

LL Schedule Designatio	n	ASCE 7 Designation		
Use	LL	LL	Description	
Gallery - Typical	100	100	Assembly Area - Typical

# FLOOR SYSTEM ANALYSIS

### OVERVIEW

Technical Report 2 analyzes and compares AAM's existing floor systems with three alternates. Each system was evaluated based on criteria such as system weight, overall depth, cost, feasibility, and impact on both the lateral and foundation systems. Other considerations unique to each system were also considered. A table summarizing these findings is in the Summary section following the four system descriptions.

Figure 13 indicates the bay that was considered "typical" for the purposes of Technical Report 2; having dimensions of 20' (E-W) x 20'-8" (N-S). The following systems are discussed below:

- Steel-Composite System
- Purlin-Girder (Non-Composite)
- One-way Slab with Beams
- Two-way Flat Slab with Drop Panels

This study does not include any precast concrete systems because the manufacturers do not include the span/loading combinations required for this building. A pre-stressed hollow-core plank, for example, would require a unique design where shear controls. Similarly, post-tensioned slab systems were not included because of the need for flexibility in the spaces above. If ever the museum were to build partitions, anchors drilled into the slab could damage the post-tensioning tendons. In an effort to accommodate a flexible use of the space per the project requirements, post-tensioned systems had to be neglected.

The weight and cost estimates were calculated as carefully as possible using the RS Means Facilities estimates (detailed) 2012. Each common assembly from the assembly book was altered to match the project and design requirements and itemized into a detailed report seen in Appendix F.

### STEEL-COMPOSITE SYSTEM

### Description

The existing floor system, shown in Figure 14, is a composite system utilizing concrete, composite metal deck, and wide-flange steel beams and girders. A technical analysis for this system was executed as member spot-checks in Technical Report 1, and the relevant calculations have been included in Appendix B of this report.

3 ¼" of lightweight concrete sits atop 3" – 18 ga. Composite decking for a total of 6 ¼". Per the calculations performed in Technical Report 1, Vulcraft specified 3VLI 18 is sufficient for the superimposed dead and live loads required, and provides a 2-hour fire rating. N-S running W14x26s with 18 shear studs support the decking every 10', while W16x36s with 36 shear studs run between the columns in the E-W direction, supporting the W14s.

### Advantages

Technical Report 2 does not address issues such as the building's form or the a-typical 70' span supporting the gallery on Level 6 technically (see Figures 3 & 4 in Introduction), but a composite system likely addressed those challenges more than those for the typical bay analyzed. Drawing S-106 in Appendix A shows that many of those longer spans are supported by W40x249s with over 200 shear studs and web openings to accommodate MEP coordination. Additionally, a lighter non-composite system would have less stiffness; the floor would be much more susceptible to vibration problems. Ultimately, the composite system was likely chosen because it costs about 55% of its congruent non-composite purlin-girder system.

### DISADVANTAGES

While the composite system described may have the advantage in cost, it weighs about 50% more than its non-composite counterpart. Also, the composite system is the second-deepest of the four analyzed. Furthermore, Vulcraft specifies the composite assembly as 2HR inherently, but the beams and girders still require fireproofing.

## ALTERNATE 1: PURLIN-GIRDER NON-COMPOSITE SYSTEM

### Description

Figure 15 displays the layout of the purlin-girder alternate designed for Technical Report 2. This analysis chose to consider a purlin-girder system as opposed to other, manufactured, lightweight flooring systems because of the large live loads. Similar to the reasoning presented against precast concrete, manufacturers do not include the load/span combinations desired for this building. In order to reduce the impact to architectural layout (changing column spacing), a purlin-girder system emerged as the solution for lightweight floor analysis. In the full design calculations in Appendix C, only the channels are assumed to be fully braced. The channels and the W18s are controlled by deflection.

The load path alters slightly from that of the existing composite system above. The 1"-24 ga. Floor decking with 2 ½" topping, specified as Vulcraft 1.0C24, still runs E-W, but spans 3' instead of 10' (see Figure 14). Next in the load path lays C8x11.5 channel sections. These channels run 10' 4" and are supported by a W18x55, which span 20' (E-W). Finally, a W24x84 distributes the loads from its midpoint to the columns, running 20' 8" (N-S).

### **A**DVANTAGES

A steel purlin-girder system is the only alternate that would allow for the geometry of the building to remain similar. The hangers and steel trusses could remain in the design scheme for a lightweight steel floor where the concrete alternatives could not. Objectively, the lightweight purlin-girder system has few additional advantages other than weight. If, for some reason, the architect and owner required minimal column profile, or the foundations had size or depth constraints, or if there was a stipulation to minimize the concrete used, the purlin-girder system may have been a viable solution. Also, it is possible that an architect or owner might insist on using this system explicitly.

### DISADVANTAGES

The purlin-girder system is the deepest of the four analyzed, and with an 11' 6" floor-to-floor height, the 27" floor depth leaves only 3" for MEP on a 9' ceiling. This constraint would have to lead to either a change in floor-to-floor or floor-to-ceiling height. Also, because the system uses the most amount of steel by volume, it is by far the most expensive of the systems. Additionally the labor required for the connections drives the cost significantly. Furthermore, the lost mass of the system results in greater susceptibility to vibration issues. To meet the fireproofing requirement of 2 hours, the girders, beams, channels, and decking would all need to be encased in fibrous-spray protection. Finally, these types of systems are not often constructed and would result in more risk, and thus even greater expense for the contractor and owner.

## ALTERNATE 2: TWO-WAY FLAT SLAB WITH DROP PANELS

### DESCRIPTION

The two-way flat slab with drop panels shown in Figure 16 below was analyzed as the second alternative floor system. Similar to the purlin girder system above, the bay size was not changed in order to control Architectural impact. Switching the floor from steel to concrete requires the frame system to change as well. Calculations found in Appendix D explore how an 18"-diameter spiral-reinforced column was designed to replace a "typical", median column capacity found in AAM's column schedule (S-120.01 in Appendix A). Once a minimum slab thickness of 6.7" was established, the flat slab system was evaluated by hand via direct design method as outlined in ACI 318-11 and using spSlab using equivalent frame method.

Calculations used  $f'_c = 4000psi$  (lightweight) and  $f_y = 70ksi$  to remain consistent with the project requirements (see Figure 11 in Materials Specifications). Because the bay is nearly square, the hand analysis designed for the most extreme moments along the column lines and detailed the reinforcement to match the most extreme conditions throughout the slab. Differences in design assumptions arose in spSlab where ACI 318-08 was the latest version available and  $f_y = 60ksi$  was the maximum stirrup strength allowed by the program. The specified reinforcement is as follows:

٠	Top Reinforcement:	no. 6 @ 8" O.C. both directions at support
-	Pottom Poinforcomont:	no $1 \otimes 9" \cap C$ both directions at mid spar

• Bottom Reinforcement: no. 4 @ 8" O.C. both directions at mid-span

Two-way shear was checked at the columns without the use of drop panels in an iteration not included in the calculations in Appendix D. These finalized calculations provided establish the 7" slab depth with 9" drops are sufficient without additional reinforcement for wide-beam shear and two-way shear at the critical locations. Additionally, minimum drop panel dimensions of 8.75" thick and 3.45' wide were rounded up to 9" and 3' 6" (3.5') for constructability.

### **A**DVANTAGES

Amongst the four systems considered, the flat slab with drop panels has the lowest overall depth and is the least expensive per square-foot. A 9" overall depth would allow for both reduction of floor-to-floor height and greater ease in MEP coordination. Also, if all of the floors were as typical as the bay considered, this would greatly reduce the cost of the structure compared to existing composite system. Furthermore, the two-way flat slab with drop panels is a very common construction.

### DISADVANTAGES

The building's geometry with large cantilevers and suspended hanger supports makes the switch to a concrete frame nearly impossible. Altering the material of AAM would result in a complete change of the building's form, layout, and gravity scheme. Also, the lateral loads would need to be considered using either moment-frame analysis or shear walls would need to replace the existing concentric braced frames. Although a less significant consideration, the two-way flat slab system weighs the most of the four systems analyzed and would significantly impact the foundation systems.

## ALTERNATE 3: ONE-WAY SLAB WITH BEAMS AND GIRDERS

### Description

This report analyzes a one-way slab with beams as a tertiary alternative to the existing composite system for AAM. To be consistent with the above investigations, the one-way slab calculations did not alter the bay dimensions. The same design assumptions were used alongside the two-way system, and the beam width was assumed to be 18" to match the concrete column diameter. Deflections were considered to be non-critical as ACI 318-11 9.5.2.1, with the appropriate adjustment factors, permits omission of these calculations.

Figure 17 below shows the framing of the one-way slab system. Its framing system is congruent to that of the purlin-girder non-composite system analyzed in alternate 1. Like the channel sections, the 5 1/2" slab runs 10' 4" (N-S) and is supported by a beam 14" deep by 18" wide. These primary beams run the 20' span to girders 16" deep by 18" wide, which span N-S to the columns. The controlling reinforcement for the one-way slab system is as follows:

- Slab: no. 3 @ 6" O.C. with no additional shear reinforcement
- 14" x 18" Beam: (4) no. 8 with (8) no. 3 stirrups @ 6" O.C. from 2" from face
- 16" x 18" Beam: (3) no. 9 with (8) no. 3 stirrups @ 6" O.C. from 6" from face

#### **A**DVANTAGES

•

The advantages of the one-way slab with beam system are similar to those of the two-way. Its overall depth is significantly less than that of the current system. Compared to the flat-slab system, it weighs nearly 10 PSF less and is only \$.05 more expensive. Also, the mass and arrangement of this system makes it the least susceptible to vibration problems. Finally, like the two-way and composite systems, the one-way slab is commonly built and would require no additional or unique scheduling considerations in a typical frame.

#### DISADVANTAGES

The disadvantages of this system are also similar to those of the two-way slab. The one-way system still weighs 15 PSF more than the current system, and would still require significant foundation alterations. Likewise, the switch to a concrete system would so drastically affect the architecture of the building's form, layout, and gravity scheme. As mentioned above, it would also require a change to a concrete lateral system. One criterion that exceeds the two-way's disadvantage is its overall depth. While MEP coordination would not be a problem for the typical bay examined, the 70' spans supporting Level 6 (S-106 in Appendix A) would likely be much deeper than the 40" for the composite system, especially if they required similar web openings.

### SUMMARY

A side-by-side comparison is in Figure 18 below. Figure 19 indicates the impact of the RS Means location factor on the overall cost of the systems. Detailed calculations of the system statistics can be found in Appendices B-D, while the weight and cost evaluations can be found in Appendix F.

	Existing	Alternatives						
Criterion	Concrete on Composite Deck and Composite Beams	Purlin-Girder (non-composite)	Two-Way Flat Slab with Drop Panels	One Way Slab on Beams

# 

Technical Report 2 evaluates the existing composite floor system against the three most viable alternatives that could have been used in the design and construction of the American Art Museum. The three alternative systems analyzed were:

- Purlin-Girder (Non-Composite)
- One-way Slab with Beams
- Two-way Flat Slab with Drop Panels

In an effort to create the most equivalent comparison, each system was evaluated on the current 20' 8" x 20' typical bay under criteria of cost, weight, depth, architectural and structural design impact, serviceability, and construction considerations.

After a thorough investigation, the existing steel-composite system emerged as the only truly viable option for this project because of considerations outside of the typical floor framing system analyzed. The form and gravity structural scheme of AAM dictate a steel frame system be used, and the lightweight floor system, though to code, would deflect 4 times that of the existing system and be highly susceptible to vibration issues. Also, the lightweight floor system could nearly double the cost of the structural steel.

If a concrete frame had been considered as part of the form and geometry of the building, the two-way flat slab with drop panels may have been considered. It is unlikely, however, that the architect and owner would have chosen a concrete system that would not provide the spans required for such open and flexible art gallery spaces – a problem for both concrete systems. Again, the drive for an iconic building with large open spaces on elevated slabs and a unique form necessitate a steel frame.

#### Reinforcement Criteria

## Slabs and Ribs

#### -----

	Top ba	ars	Bottom b	ars		
	Min	Max	Min	Max		
Bar Size	#4	#8	#4	#8		
Bar spacing	1.00	12.00	1.00	12.00	in	
Reinf ratio	0.14	5.00	0.14	5.00	%	
Cover	0.75		0.75		in	
There is NOT	more than	12 in	of concrete	below	top	bars.

### Beams

	Top bars		Bottom	bars	sti	Stirrups		
	Min	Max	Min	Max	Min	Max		
Bar Size	#5	#8	#5	#8	#3	#5		
Bar spacing	1.00	18.00	1.00	18.00	6.00	18.00	in	
Reinf ratio	0.14	5.00	0.14	5.00	%			
Cover	1.50		1.50		in			
Layer dist.	1.00		1.00		in			
No. of legs					2	6		
Side cover					1.50		in	
1st Stirrup					3.00		in	
There is NO	T more th	an 12 in	of concret	te below	top bars.			

#### [2] DESIGN RESULTS\*

#### \_\_\_\_\_

\*Unless otherwise noted, all results are in the direction of analysis only. Another analysis in the perpendicular direction has to be carried out for two-way slab systems.

#### Strip Widths and Distribution Factors

Units: Width (ft).

		_Width		Moment Factor				
Span Strip	Left**	Right**	Bottom*	Left**	Right**	Bottom*		
1 Column	10.17	10.00	10.17	1.000	0.750	0.600		
Middle	9.83	10.00	9.83	0.000	0.250	0.400		
2 Column	10.00	10.00	10.00	0.750	0.750	0.600		
Middle	10.00	10.00	10.00	0.250	0.250	0.400		
3 Column	10.00	10.17	10.17	0.750	1.000	0.600		
Middle	10.00	9.83	9.83	0.250	0.000	0.400
