List of Figures

1.1	Satellite image of Glacier Bay National Park. Photo credit: NASA (http://glacier-bay.gsfc.nasa.gov/).	12
1.2	Glacier coverage in 1700; source: Glacier Bay Ecosystem CD. .	13
1.3	Glacier coverage in 1985; source: Glacier Bay Ecosystem CD. .	14
1.4	Conceptual model of the major oceanographic processes in Glacier Bay. Figure is reproduced from Hooge & Hooge (2002) , and is based upon a figure from Syvitski <i>et al.</i> (1987)	15
2.1	Finite element mesh of the region near the Beardslee Islands. .	18
2.2	File folder structure obtained after unzipping ADCIRC source code.	20
2.3	Graphical user interface of the ssh client.	21
3.1	Graphical output from the Coastline Extractor program indicating the coastline data in the vicinity of Glacier Bay.	28
3.2	Graphical output from GEODAS indicating the bathymetry data obtained for the Glacier Bay region. The solid red line indicates the bounding polygon identified by the user. The light gray lines indicate coastlines and the heavier black lines indicate individual data sets.	29
3.3	Scatter plot of domain bathymetry.	30
3.4	Incorrect data (red dots in the main channel) in the vicinity of Gustavus, AK.	31
3.5	Reduced domain shoreline, with open boundaries placed at the Gulf of Alaska and the Lynn Canal.	32
3.6	Illustration of original vs. smoothed shoreline data. Area shown is Berg Bay.	33
3.7	Structure of the .poly file required by BATTRI.	35
3.8	Sample domain and corresponding .poly file.	36

3.9	Intermediate plot output from BATTRI. The area shown is Charpentier Inlet; the blue dots and red lines indicate the boundary as specified by the .poly file, the blue x marks indicate user added interior points.	37
3.10	Sample mesh, as generated by BATTRI, for Tarr Inlet.	38
3.11	Refined (final) mesh for Glacier Bay and Icy Strait / Cross Sound.	44
3.12	Histograms of grid element parameters.	45
3.13	Histograms of grid element parameters.	46
5.1	Locations of weather stations used in determining rainfall and temperature values.	54
5.2	Digital elevation data for Glacier Bay National Park.	57
5.3	Forest cover, superimposed upon the elevation DEM.	58
5.4	Snow / ice cover, superimposed upon the elevation DEM.	59
5.5	Point and line watersheds, ad delineated with GIS analysis, for the Glacier Bay domain.	60
5.6	Streamflow analysis regions for Alaska. Figure reproduced from Curran et al. (2003)	68
5.7	Flow duration curve for the Glacier Bay domain.	69
5.8	Normalized annual precipitation and runoff for the Gulf of Alaska from Wang et al. (2004) . The hydrograph of Royer (1979) , as determined from the meteorological data in Wang et al. (2004) is also shown.	70
5.9	71
5.10	Modeled annual hydrograph for Glacier Bay Domain.	72
6.1	Select climate data stations in the vicinity of Glacier Bay.	74
6.2	Plot of surface pressure over an 18 year period. Also shown is the data, binned hourly and averaged over the 18 year period of the record.	75
7.1	User selection of the fort.61 stations to plot as time series.	79
7.2	Time series of water surface elevation for the selected station(s).	80
7.3	Sample contour plot of free surface elevation at a given simulation time.	81

7.4	Sample velocity vectors showing the two-dimensional flow field and contours of bathymetric depth in the Sitakady Narrows area.	82
7.5	Sample velocity vectors showing the two-dimensional flow field and contours of water speed in the Sitakady Narrows area. . .	83
7.6	Sample particle trajectories, based upon the Euler method, using small and large time steps. Also shown are the exact trajectories.	88
7.7	Sample particle trajectories, based upon the Runge-Kutta method, using small and large time steps. Also shown are the exact trajectories. Note that the time steps used are the same as in Fig. 7.6.	89
7.8	Particle trajectories, in the Beardslee Islands area, calculated with both the Euler (solid lines) and the Runge-Kutta methods (dots).	90
8.1	Comparison of output from a 7 day and a 14 day simulation. Also shows is the absolute value of the difference between the two runs.	94
8.2	Interactive map allowing for the extraction of historic tidal data and tidal predictions.	95
8.3	Comparison of NOAA predictions and ADCIRC calculations at the Elfin Cove Station for the 14 day period beginning 6/25/2002.	96
8.4	Comparison of NOAA predictions, ADCIRC calculations, and observational data at the Elfin Cove Station for the 14 day period beginning 1/1/2006.	97
9.1	Domain map indicating five stations specified for time series output.	99
9.2	Domain map indicating five stations specified for time series output.	100
9.3	Color contours of water surface elevation.	101
9.4	Color contours of water surface elevation in Glacier Bay proper.	102
9.5	Color contours of MHHW in meters.	104
9.6	Color contours of MLLW in meters.	105
9.7	Color contours of tidal range in meters.	106

9.8	Sample velocity vectors showing the two-dimensional flow field and contours of water speed in the Sitakady Narrows area.	108
9.9	Illustration of complex eddying in Sitakaday Narrows, between Young Island and Rush Point.	109
9.10	Color contours of root mean square tidal speed.	112
9.11	Color contours of root mean square tidal speed in the Sitakaday Narrows area.	113
9.12	Location of oceanographic data collection stations. Figure reproduced from Etherington <i>et al.</i> (2004)	114
9.13	Particle trajectories for trial 2 for the entire domain.	118
9.14	Particle trajectories for trial 2 for the lower bay region.	119
9.15	Particle trajectories for trial 1 for the lower bay region.	120
9.16	Particle trajectories for trial 4 for the lower bay region.	121
9.17	Particle trajectories for trial 3 for the lower bay region.	122
9.18	Particle trajectories for spring tides in the Beardslee Islands area.	123
9.19	Wind speed and direction data for the period in question.	127
9.20	Model domain, with the five recording stations identified.	128
9.21	Normalized absolute value of the difference between the ‘wind’ and ‘no wind’ x and y components of velocity.	129
9.22	Normalized absolute value of the difference between the ‘wind’ and ‘no wind’ calculations of water surface elevation.	130
9.23	Particle trajectories, for spring tide conditions, as calculated in the presence (red markers) and absence (blue markers) of freshwater input. Tracks correspond to three hours of simulation time.	133
9.24	Particle trajectories, for spring tide conditions, as calculated in the presence (red markers) and absence (blue markers) of freshwater input. Tracks correspond to two days of simulation time.	134

List of Tables

5.1	Mean annual precipitation (MAP) and mean minimum January temperature (MMJT) values for weather stations in the vicinity of Glacier Bay.	55
5.2	Regression equations (for regions 1 and 3) for various recurrence intervals. Q_T is the discharge in cfs, A is drainage area in square miles, ST is the area of lakes and ponds in percent, P is the mean annual precipitation in inches, J is the mean minimum January temperature in degrees Fahrenheit. Equations are taken from Curran <i>et al.</i> (2003)	62
5.3	Peak discharge values, for various recurrence intervals, for the Glacier Bay domain.	63
5.4	Regression equations (for regions 1 and 3) for annual high duration flows. OS_n is the discharge, having an n percent exceedence probability, in cfs, A is drainage area in square miles and P is the mean annual precipitation in inches. Equations are taken from (Wiley & Curran, 2003 , Table 2)	64
5.5	Regression equations (for region 1) for annual low duration flows. $J-S_n$ is the discharge, having an n percent exceedence probability, in cfs, A is drainage area in square miles, P is the mean annual precipitation in inches, and E is the mean basin elevation in feet. Equations are taken from (Wiley & Curran, 2003 , Table 2)	65
5.6	Normalized mean monthly flows for several USGS gaging stations in southeast Alaska	66
9.1	Root mean square tidal speeds at USGS oceanographic station locations.	115
9.2	Summary of trajectory information for particles released at 5 stations within the domain.	126

Preface

The work described in this report is the result of a 10 day kayak trip in Glacier Bay during the summer of 2004 and a healthy dose of serendipity. On the way to an up-bay drop off point, the author overheard two other kayakers discussing acoustic doppler current profilers. This is decidedly *not* in the lexicon of your average kayaker and it certainly caught the ear of the author. The ensuing conversation with Dr. Lisa Etherington (then of the U.S.G.S.) and a well-timed sabbatical leave granted by the Pennsylvania State University to the author during the 2005-2006 academic year are responsible for the following pages.

The author is indebted to Dr. Etherington for her interest in and enthusiasm for a hydrodynamic study of the tides in Glacier Bay and for her provision of many useful data and reports regarding the Bay. Additional thanks are due to Jennifer Mondragon, Erika Madison, and Jennifer Fisher, all of whom provided valuable physical data to the author. This work was financially supported, in part, through a grant from the National Park Service. The author would like to also acknowledge the significant assistance he received from Lewis Sharman of the NPS. Finally, financial assistance from the U.S.G.S. allowed the author to attend and participate in the 2004 Glacier Bay Science Symposium.

This report serves two very different purposes and two very different audiences. On the one hand, it is a ‘user’s guide’ of sorts, laying out, in rather extensive detail, the steps involved in running simulations of the tidal flows in Glacier Bay. These steps involve extensive pre-processing, parallel computations on a Linux cluster, and extensive post-processing and data visualization. The path taken by the author relied heavily on freely-available software and data and this report should assist other researchers similarly interested in conducting open-source numerical studies of tidal circulation.

On the other hand, the report serves the non-specialist who is interested in the ‘big picture’ of tides in the Bay. Biologists and ecologists stand to benefit from an appreciation of circulations in the bay. Model runs have produced extensive data sets which are easily queried in order to produce information on tidal elevations, water velocities, and particle trajectories.

Summary

A tidal circulation model (ADCIRC) has been adapted to Glacier Bay National Park. The model domain includes Glacier Bay proper and the outlying waters of Icy Strait and Cross Sound. A very high spatial resolution was used in constructing the model domain, allowing for the resolution of many of the small islands and tidal channels in the bay.

The model is forced with tides at the open boundaries in the Gulf of Alaska and Lynn Canal, meteorological conditions, and freshwater inputs. Presently, model runs are two-dimensional (depth integrated), allowing for accurate simulation of the water surface elevation and barotropic tidal velocities.

Model output includes time series of elevation and velocity at specified locations, global elevation and velocity output, and harmonic analysis of these fields. The simulations have been validated against tidal data and known tidal constituents and have shown very good agreement.

Specific results of interest include predictions of tidal datums, such as mean high water, tidal range, etc., at all points in the model domain. Additionally, calculations of root-mean-square tidal speed have been made and are indicative of regions of strong tidal mixing. Lagrangian particle tracking has been performed and demonstrates the dramatic variability in tidal excursions in the bay.

The ADCIRC model is open source and the pre- and post-processing tools developed by the author are also freely available. The net effect of this is a modeling package that is available to any interested scientist.

Future work on this project is centered upon extending the model to three dimensions. Given the strong freshwater inputs to Glacier Bay and the documented strong vertical stratification, this step is essential to a full understanding of the baroclinic currents in the bay.
